ASP.NET Core CRUD Web API

Hans-Petter Halvorsen

Contents

- We will create a simple “Web API” using **ASP.NET**.
 - ASP.NET is a server-side framework for creating web pages and web contents.
 - We will use **SQL Server** as the Database system.
 - We will implement a simple **CRUD** Web API that Create, Read, Update and Delete data in the Database.
 - We will use **Visual Studio** as the Code editor.
- Finally, we will use **Python** and **Thonny** editor to test the Web API.

<https://www.halvorsen.blog>

Introduction

Hans-Petter Halvorsen

API

- Application Programming Interface (API).
- An API is a way for two or more computer programs or components to communicate with each other.
- It is a type of software interface that offers a service to other software.
- APIs come in many shapes, some examples are SOAP API, REST API, Web API, GraphQL API, etc.
- Most programming languages today have components/libraries that can be used both to create APIs and to consume APIs (using existing APIs).

Web API

- We can create/use APIs for internal use inside an Application or between 2 or more Applications.
- Basically, an API can be just a Class with Methods that you use several places inside an Application or that you share between multiple Applications.
- A set of Stored Procedures in a Database can also be an API.
- When the Application that consume/use the API is on a local PC and the API itself is located on a Server, we can talk about so-called “Web APIs”.
- Such Web APIs also very often perform CRUD operations against a Database located on the Web.
- Note! Normally it is not allowed to connect directly to a Database located in the Cloud from a local computer unless you configure and give access to the IP addresses for those clients.

Web API

Normally it is not allowed to connect directly to a Database located in the Cloud from a local computer unless you configure and give access to the IP addresses for those clients.

JSON

- When it comes to Web APIs and REST APIs JSON is the standard for the data format.
- Example:

```
{  
  "Name": "John Wayne",  
  "Work": "Actor",  
  "Age": 52  
  "Children": [  
    "Lisa",  
    "Thomas",  
    "Knut"  
  ]  
}
```

Why use Web API?

- Normally it is not allowed to connect directly to a Database located in the Cloud from a local computer
 - unless you configure and give access to the IP addresses for those clients.
 - Typically, your IT Department don't allow that
- You can use the same API for multiple Applications, let say you have a Desktop App, an iPhone App and an Android App
 - All can use the same API
 - You save time and money by developing only once instead of specific code for each application.
- You want to expose data to external services or persons, e.g., a Weather API that can be used by persons, external apps or services. Other examples: Hotel/plane reservations and ticket systems

API Summary

- “Web APIs”, “REST APIs” or “HTTP APIs” are basically the same.
- It is more or less just different names for the same.
- They all communicate via Internet and use **HTTP** as communication protocol.
- And they use JSON (or sometimes XML) as Data Format.
- Very often they implement CRUD functionality.

<https://www.halvorsen.blog>

ASP.NET Web API Example

Hans-Petter Halvorsen

Example

We will create a Web API with CRUD functionality, meaning we will insert, read, update and delete data in a Database.

- We will start by creating a Database and Table using **SQL Server** and SQL Server Management Studio.
- Then we will create the **ASP.NET** code for the Web API.
- We will test the API in the URL in the Web Browser.
- Finally we will test the API creating some basic **Python** examples.

Tools

The following tool will be used in this example:

- SQL Server
 - SQL Server Management Studio
- Visual Studio
- ASP.NET
- Python
 - Thonny Python Editor

Database

```
CREATE TABLE [AUTHOR]
```

```
(  
    [AuthorId] [int] IDENTITY(1, 1) NOT NULL PRIMARY KEY,  
    [AuthorName] [varchar](50) NOT NULL UNIQUE,  
    [Address] [varchar](50) NULL,  
    [Phone] [varchar](50) NULL,  
    [PostCode] [varchar](50) NULL,  
    [PostAddress] [varchar](50) NULL,  
)
```

```
CREATE TABLE [BOOK]
```

```
(  
    [BookId] [int] IDENTITY(1, 1) NOT NULL PRIMARY KEY,  
    [Title] [varchar](50) NOT NULL UNIQUE,  
    [ISBN] [varchar](20) NOT NULL,  
    [PublisherId] [int] NOT NULL FOREIGN KEY REFERENCES PUBLISHER(PublisherId),  
    [AuthorId] [int] NOT NULL FOREIGN KEY REFERENCES AUTHOR(AuthorId),  
    [CategoryId] [int] NOT NULL FOREIGN KEY REFERENCES CATEGORY(CategoryId),  
    [Description] [varchar](1000) NULL,  
    [Year] [date] NULL,  
    [Edition] [int] NULL,  
    [AverageRating] [float] NULL,  
)
```

```
CREATE TABLE [PUBLISHER]
```

```
(  
    [PublisherId] [int] IDENTITY(1, 1) NOT NULL PRIMARY KEY,  
    [PublisherName] [varchar](50) NOT NULL UNIQUE,  
    [Description] [varchar](1000) NULL,  
    [Address] [varchar](50) NULL,  
    [Phone] [varchar](50) NULL,  
    [PostCode] [varchar](50) NULL,  
    [PostAddress] [varchar](50) NULL,  
    [Email] [varchar](50) NULL,  
)
```

```
CREATE TABLE [CATEGORY]
```

```
(  
    [CategoryId] [int] IDENTITY(1, 1) NOT NULL PRIMARY KEY,  
    [CategoryName] [varchar](50) NOT NULL UNIQUE,  
    [Description] [varchar](1000) NULL,  
)
```

Visual Studio

Book Class

```
using System;
using System.Collections.Generic;
using System.Data;
using Microsoft.Data.SqlClient;

namespace BookApp.Models
{
    public class Book
    {
        public int BookId { get; set; }
        public string Title { get; set; }
        public string Isbn { get; set; }
        public string PublisherName { get; set; }
        public string AuthorName { get; set; }
        public string CategoryName { get; set; }

        public List<Book> GetBooks(string connectionString) {
            ..
        }

        public Book GetBookData(string connectionString, int bookId) {
            ..
        }

        public void CreateBook(string connectionString, Book book) {
            ..
        }

        public void EditBook(string connectionString, Book book) {
            ..
        }

        public void DeleteBook(string connectionString, int bookId) {
            ..
        }
    }
}
```

API “Methods”

We create the following API CRUD methods

- Books
- GetBook?BookId={id}
- NewBook
- EditBook
- DeleteBook?BookId={id}

Running API in Visual Studio

Books

This method is used to retrieve All Books from the Database

Hans-Petter Halvorsen

GetBooks - C# Method

Book.cs

```
public List<Book> GetBooks(string connectionString)
{
    List<Book> bookList = new List<Book>();

    SqlConnection con = new SqlConnection(connectionString);
    string selectSQL = "select BookId, Title, Isbn, PublisherName, AuthorName, CategoryName from GetBookData";
    con.Open();

    SqlCommand cmd = new SqlCommand(selectSQL, con);
    SqlDataReader dr = cmd.ExecuteReader();

    if (dr != null)
    {
        while (dr.Read())
        {
            Book book = new Book();

            book.BookId = Convert.ToInt32(dr["BookId"]);
            book.Title = dr["Title"].ToString();
            book.Isbn = dr["ISBN"].ToString();
            book.PublisherName = dr["PublisherName"].ToString();
            book.AuthorName = dr["AuthorName"].ToString();
            book.CategoryName = dr["CategoryName"].ToString();

            bookList.Add(book);
        }
    }
    return bookList;
}
```

Books API Code

Books.cshtml

```
public JsonResult OnGet()
{
    List<Book> books = new List<Book>();

    books = GetBookList();
    return new JsonResult(books);
}

private List<Book> GetBookList()
{
    connectionString = _configuration.GetConnectionString("ConnectionString");

    List<Book> bookList = new List<Book>();

    Book book = new Book();

    bookList = book.GetBooks(connectionString);

    return bookList;
}
```

Books - Web Browser

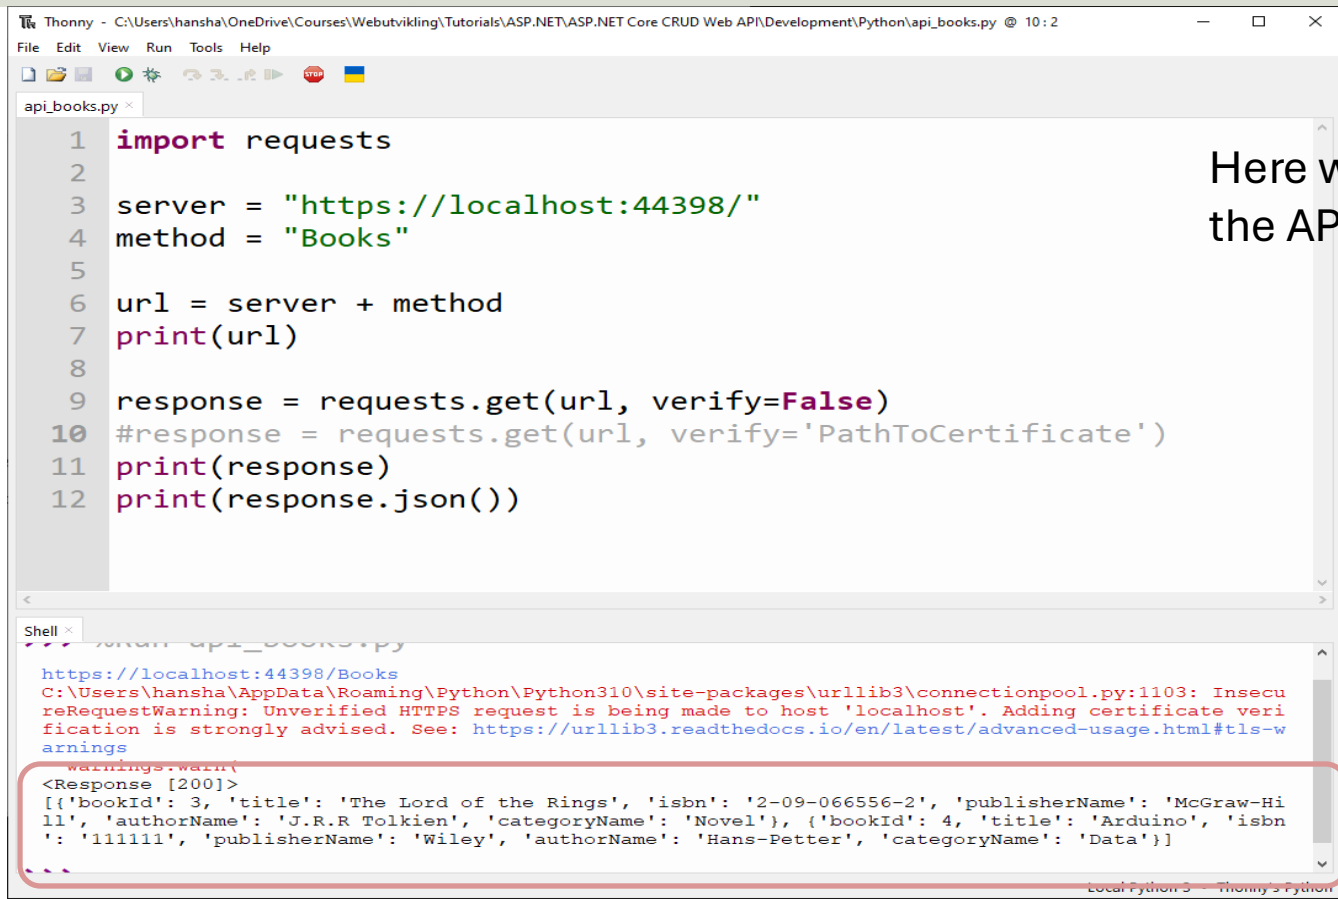

Pretty-print ☒

```
[
  {
    "bookId": 2,
    "title": "Modern Control System",
    "isbn": "1-08-890781-0",
    "publisherName": "Wiley",
    "authorName": "Dorf Bishop",
    "categoryName": "Programming"
  },
  {
    "bookId": 3,
    "title": "The Lord of the Rings",
    "isbn": "2-09-066556-2",
    "publisherName": "McGraw-Hill",
    "authorName": "J.R.R Tolkien",
    "categoryName": "Novel"
  }
]
```

There are 2 books in the database at the moment.

<https://localhost:44398/Books>

Books - Thonny

The screenshot shows the Thonny IDE interface. The top window, titled 'api_books.py', contains a Python script that uses the 'requests' library to fetch data from a local API. The script defines a server URL, a method, constructs a full URL, and sends a GET request. The response is printed as JSON. The bottom window, titled 'Shell', shows the output of the script, including a warning about an unverified HTTPS request and a list of book data.

```
Thonny - C:\Users\hansha\OneDrive\Courses\Webutvikling\Tutorials\ASP.NET\ASP.NET Core CRUD Web API\Development\Python\api_books.py @ 10:2
File Edit View Run Tools Help
api_books.py
1 import requests
2
3 server = "https://localhost:44398/"
4 method = "Books"
5
6 url = server + method
7 print(url)
8
9 response = requests.get(url, verify=False)
10 #response = requests.get(url, verify='PathToCertificate')
11 print(response)
12 print(response.json())

Shell
https://localhost:44398/Books
C:\Users\hansha\AppData\Roaming\Python\Python310\site-packages\urllib3\connectionpool.py:1103: InsecureRequestWarning: Unverified HTTPS request is being made to host 'localhost'. Adding certificate verification is strongly advised. See: https://urllib3.readthedocs.io/en/latest/advanced-usage.html#tls-warnings
  warnings.warn(
<Response [200]>
[{'bookId': 3, 'title': 'The Lord of the Rings', 'isbn': '2-09-066556-2', 'publisherName': 'McGraw-Hill', 'authorName': 'J.R.R Tolkien', 'categoryName': 'Novel'}, {'bookId': 4, 'title': 'Arduino', 'isbn': '111111', 'publisherName': 'Wiley', 'authorName': 'Hans-Petter', 'categoryName': 'Data'}]
```

Here we use (consume)
the API from Python

Books - Python

```
import requests

server = "https://localhost:44398/"
method = "Books"

url = server + method
print(url)

response = requests.get(url, verify=False)
print(response)
print(response.json())
```

<https://www.halvorsen.blog>

GetBook

This method is used to retrieve a specific Book from the Database

Hans-Petter Halvorsen

GetBookData - C# Method

Book.cs

```
public Book GetBookData(string connectionString, int bookId)
{

    SqlConnection con = new SqlConnection(connectionString);
    string selectSQL = "select BookId, Title, Isbn, PublisherName, AuthorName, CategoryName from GetBookData where BookId"
                      = " + bookId;

    con.Open();
    SqlCommand cmd = new SqlCommand(selectSQL, con);
    SqlDataReader dr = cmd.ExecuteReader();

    Book book = new Book();

    if (dr != null)
    {
        while (dr.Read())
        {
            book.BookId = Convert.ToInt32(dr["BookId"]);
            book.Title = dr["Title"].ToString();
            book.Isbn = dr["ISBN"].ToString();
            book.PublisherName = dr["PublisherName"].ToString();
            book.AuthorName = dr["AuthorName"].ToString();
            book.CategoryName = dr["CategoryName"].ToString();
        }
    }
    return book;
}
```

GetBook API Code

GetBook.cshtml

```
public JsonResult OnGet()
{
    int bookId;

    bookId = Convert.ToInt16(Request.Query["bookid"]);

    Book book = new Book();

    connectionString =
        _configuration.GetConnectionString("ConnectionString");

    book = book.GetBookData(connectionString, bookId);

    return new JsonResult(book);
}
```

GetBook - Web Browser

GetBook - Thonny

The screenshot shows the Thonny IDE interface. The top window displays a Python script named `api_getbook.py` with the following code:

```
1 import requests
2
3 server = "https://localhost:44398/"
4 method = "GetBook"
5
6 bookId = "3"
7 query = "?BookId=" + bookId
8
9 url = server + method + query
10 print(url)
11
12 response = requests.get(url, verify=False)
13 print(response)
14 print(response.json())
```

To the right of the code, a text annotation reads: "Here we use (consume) the API from Python".

The bottom window, titled "Shell", shows the execution of the script:

```
>>> %Run api_getbook.py
https://localhost:44398/GetBook?BookId=3
C:\Users\hansha\AppData\Roaming\Python\Python310\site-packages\urllib3\connectionpool.py:1103: InsecureRequestWarning: Un
verified HTTPS request is being made to host 'localhost'. Adding certificate verification is strongly advised. See: https
://urllib3.readthedocs.io/en/latest/advanced-usage.html#tls-warnings
warning: user/
<Response [200]>
{'bookId': 3, 'title': 'The Lord of the Rings', 'isbn': '2-09-066556-2', 'publisherName': 'McGraw-Hill', 'authorName': 'J
.R.R Tolkien', 'categoryName': 'Novel'}
>>>
```

A red rectangular box highlights the JSON response output in the shell.

GetBook - Python

```
import requests

server = "https://localhost:44398/"
method = "GetBook"

bookId = "3"
query = "?BookId=" + bookId

url = server + method + query
print(url)

response = requests.get(url, verify=False)
print(response)
print(response.json())
```

<https://www.halvorsen.blog>

NewBook

This method is used to retrieve All Books from the Database

Hans-Petter Halvorsen

CreateBook – C# Method

Book.cs

```
public void CreateBook(string connectionString, Book book)
{
    try
    {
        using (SqlConnection con = new SqlConnection(connectionString))
        {
            SqlCommand cmd = new SqlCommand("CreateBook", con);
            cmd.CommandType = CommandType.StoredProcedure;

            cmd.Parameters.Add(new SqlParameter("@Title", book.Title));
            cmd.Parameters.Add(new SqlParameter("@Isbn", book.Isbn));
            cmd.Parameters.Add(new SqlParameter("@PublisherName", book.PublisherName));
            cmd.Parameters.Add(new SqlParameter("@AuthorName", book.AuthorName));
            cmd.Parameters.Add(new SqlParameter("@CategoryName", book.CategoryName));

            con.Open();
            cmd.ExecuteNonQuery();
            con.Close();
        }
    }
    catch (Exception ex)
    {
        throw ex;
    }
}
```

NewBook API Code

NewBook.cshtml

```
public JsonResult OnGet()
{
    Book book = new Book();

    book.Title = Request.Query["Title"];
    book.Isbn = Request.Query["Isbn"];
    book.PublisherName = Request.Query["Publisher"];
    book.AuthorName = Request.Query["Author"];
    book.CategoryName = Request.Query["Category"];

    connectionString =
        _configuration.GetConnectionString("ConnectionString");

    book.CreateBook(connectionString, book);

    return new JsonResult("Book inserted successfully");
}
```

C:\Users\hansha\AppData\Roaming\Python\Python310\site-packages\urllib3\connectionpool.py:1103: InsecureRequestWarning: Un
verified HTTPS request is being made to host 'localhost'. Adding certificate verification is strongly advised. See: https
://urllib3.readthedocs.io/en/latest/advanced-usage.html#tls-warnings
warnings.warn(
<Response [200]>
Book deleted successfully
```

A red rectangle highlights the final two lines of the shell output: `<Response [200]>` and `Book deleted successfully`.

Local Python 3 • Thonny's Python

DeleteBook - Python

```
import requests

server = "https://localhost:44398/"
method = "DeleteBook"

bookId = "19"
query = "?BookId=" + bookId

url = server + method + query
print(url)

response = requests.get(url, verify=False)
print(response)
print(response.json())
```

Summary

Hans-Petter Halvorsen

Web API Structure

Make sure to keep a good folder structure. Sooner or later, you will have multiple APIs, and you also probably need to maintain multiple versions of the same API, e.g., like this:

- API
 - Book
 - 1.0
 - » PHP API Files
 - 2.0
 - » PHP API Files
 - Customer
 - 1.0
 - » PHP API Files
 - ..

Basic Security and Access Control

- It is a good idea to add some security and access control.
- In that way only users that has access can get, insert, update or delete data.
- You then need to add a basic check in your PHP files to check if password is correct.

Example:

https://server/api/book/1.0/DeleteBook.php?api_key=xxx&id=20

PHP Example

Test in Web Browser

<https://server/api/book/1.0/DeleteBook.php?key=Password1234&id=21>

Python

The screenshot shows the Thonny Python IDE interface. The top window displays a Python script named `api_deletebook.py` with the following code:

```
1 import requests
2
3 server = "https://web01.usn.no/~hansha/"
4 api = "api/book/1.0/"
5 method = "DeleteBook"
6
7 key = "Password1234"
8 id = "19"
9 query = "?key=" + key + "&id=" + id
10
11 url = server + api + method + ".php" + query
12 print(url)
13
14 response = requests.get(url)
15 print(response)
16 print(response.json())
```

The bottom window, titled "Shell", shows the execution of the script:

```
>>> %Run api_deletebook.py
api/book/1.0/DeleteBook.php?key=Password1234&id=19
<Response [200]>
{'message': 'You dont have access'}
```

The status bar at the bottom right indicates "Local Python 3 • Thonny's Python".

Summary

- We have created a simple Web API using ASP.NET Core.
- We tested the Web API using Python.
- In general, we can use any kind of programming language to interact with this API.
 - E.g., we can create a Windows Forms Application in Visual Studio and C#.
- In that way we can insert, read, update or delete data in the remote database from a local application.
- Normally you cannot directly interact with a remote SQL Database from your local computer due to security reasons.
- There are lots of improvements to be made to make a better code structure (create classes, etc.), make it more robust with error handling, improved security, etc. But I leave that to you to improve.
- The code is made simple to illustrate the basic principles using Web APIs.
